## 1. Introduction and Preliminaries

Professor V. Popa [6] has used the concept of a rare set (a set  $R$  is *rare* if  $\text{Int}(R) = \emptyset$ ) to define a rarely continuous function as follows:

**Definition 1.1** ([Long and Herrington], [Popa]) A function  $f: X \rightarrow Y$  is *rarely continuous* at  $x \in X$  if for each open  $V$  containing  $f(x)$  there exists a rare set  $R_V$  with  $\text{Cl}(R_V) \cap V = \emptyset$  and an open  $U$  containing  $x$  such that  $f(U) \subset V \setminus R_V$ . And  $f$  is called rarely continuous if it is so at each  $x$  in  $X$ .

The purpose of this paper is to further investigate fundamental properties of such functions. Rarely continuous functions are a natural extension of weakly continuous functions.

**Definition 1.2** ([Taqdir Husain]) (1) A function  $f: X \rightarrow Y$  is *weakly continuous* at  $x$  in  $X$  if for each open  $V$  containing  $f(x)$  there exists an open  $U$  containing  $x$  such that  $f(U) \subset \text{Cl}(V)$ . (2) A function  $f: X \rightarrow Y$  is said to be *nearly continuous* at  $x$  in  $X$  if for each neighborhood  $V$  of  $f(x)$  there is a neighborhood  $U$  of  $x$  such that  $f(U) \subset \text{Int}(\text{Cl}(V))$ .

Evidently, every weakly continuous function is rarely continuous but the converse is not true ([Long and Herrington]).

**Definition 1.3** ([Takashi Noiri, 1978]) A subset  $S$  of a space  $X$  is said to be  *$N$ -closed* to  $X$  if for every cover  $\{U_\alpha : \alpha \in \Delta\}$  of  $S$  by open sets of  $X$ , there exists a finite subfamily  $\nabla_0$  of  $\Delta$  such that

$$S \subset \{ \text{Int}(\text{Cl}(U_\alpha)) : \alpha \in \nabla \}.$$

If  $X$  is  $N$ -closed relative to  $X$ , then it is called *nearly-compact*.

We refer the other definitions to [Taqdir Husain].

**Lemma 1.4** ([Long and Herrington, theorem]) Let  $f : X \rightarrow Y$  be a function. Then the followings are equivalent:

- (a)  $f$  is rarely continuous at  $x$  in  $X$ .
- (b) For each open  $V$  containing  $f(x)$  there exists a rare set  $R_v$  with  $R_v \cap \text{Cl}(V) = \emptyset$  and an open  $U$  containing  $x$  such that  $f(U) \subset \text{Cl}(V) \cup R_v$ .
- (c) For each regular-open  $V$  containing  $f(x)$  there exists a rare set  $R_v$  with  $\text{Cl}(R_v) \cap V = \emptyset$  and an open  $U$  containing  $x$  such that  $f(U) \subset V \cup R_v$ .

## 2. Properties on Rarely Continuous Functions

**Theorem 2.1.** A function  $f : X \rightarrow Y$  is rarely continuous if and only if for each open set  $V$  in  $Y$ , there exists a rare set  $R_v$  such that  $f^{-1}(V) \subset \text{Int}(f^{-1}(V \cup R_v))$ .

**Proof.** If  $f$  is rarely continuous, then for each open  $V$  of  $Y$  with  $f(x) \in V$ , there exists a rare set  $R_v$  such that  $\text{Cl}(V) \cap R_v = \emptyset$  and there exists an open set  $U$  containing  $x$  such that  $f(U) \subset V \cup R_v$ , which implies  $U \subset f^{-1}(V \cup R_v)$  and hence  $x \in U \subset \text{Int}(f^{-1}(V \cup R_v))$ .

Since  $x \in f^{-1}(V)$ ,

$$f^{-1}(V) \subset \text{Int}(f^{-1}(V \cup R_v)).$$

Conversely, if for each open set  $V \subset Y$ , there exists a rare set  $R_v$  with  $\text{Cl}(V) \cap R_v = \emptyset$  such that  $f^{-1}(V) \subset \text{Int}(f^{-1}(V \cup R_v))$ .

Then by putting

$$U = \text{Int}(f^{-1}(V \cup R_v)),$$

we see that

$$\begin{aligned} f(x) \in f(U) &= f(\text{Int}(f^{-1}(V \cup R_v))) \\ &\subset f f^{-1}(V \cup R_v) \\ &\subset V \cup R_v. \end{aligned}$$

Hence  $f$  is rarely continuous by Lemma 1.4 (b).

**Theorem 2.2** Let  $\{P_\alpha\}$  be an open covering of a topological space  $X$ ,  $Y$  a topological space, and  $f$  a function of  $X$  into  $Y$ . If for each  $\alpha$ , the restriction  $f|P_\alpha : P_\alpha \rightarrow Y$  is rarely continuous then  $f$  is rarely continuous.

**Proof.** Let  $x \in X$ . Then there exists  $\alpha$  such that  $x \in P_\alpha$ . Let  $V$  be a regular-open subset of  $Y$  containing  $f(x)$ . Since the restriction  $f|P_\alpha = f_\alpha$  is rarely continuous, there exists a rare set  $R_v$  with  $\text{Cl}(R_v) \cap V = \emptyset$  and an open  $U$  in  $P_\alpha$  containing  $x$  such that  $f(U) \subset V \cup R_v$ . But then there is an open subset  $W$  of  $X$  such that

$$x \in U = W \cap P_\alpha.$$

But since  $U$  is an open set in  $X$  (because  $W$  and  $P_\alpha$  are open in  $X$ ), it follows that  $f : X \rightarrow Y$  is rarely continuous by lemma 1.4(c).

**Theorem 2.3.** If  $f : X \rightarrow Y$  is an almost continuous function and

$$\text{Cl}(f^{-1}(V)) \subset f^{-1}(V \cup R_v)$$

for each open  $V$  with rare set  $R_v$  such that  $\text{Cl}(R_v) \cap V = \emptyset$  then  $f$  is rarely continuous.

**Proof.** For any point  $x$  in  $X$  and any open set  $V \subset Y$  containing  $f(x)$ , by the hypothesis we have  $\text{Cl}(f^{-1}(V)) \subset f^{-1}(V \cup R_v)$ .

Since  $f$  is almost continuous, there exists an open  $U$  in  $X$  such that

$$x \in U \subset \text{Cl}(f^{-1}(V)).$$

Therefore  $f(U) \subset V \cup R_v$ . That is,  $f$  is rarely continuous.

**Proposition 2.4.** An open rarely continuous function of a topological space  $X$  into a regular

space  $Y$  is continuous.

**Proof.** Let  $f : X \rightarrow Y$  be an open rarely continuous function. Let  $V$  be an open neighborhood of  $f(x)$  for  $x$  in  $X$ . Since  $Y$  is regular, there is an open neighborhood  $W$  of  $f(x)$  such that  $W \subset \overline{W} \subset V$ . Since  $f$  is rarely continuous, there is a rare set  $R_w$  with  $Cl(R_w) \cap W = \emptyset$  and an open neighborhood  $U$  of  $x$  such that

$$f(x) \in f(U) \subset W \cup R_w.$$

Since  $f$  is open function,  $f(U)$  is open set and so  $f(U) \subset Int(W \cup R_w) = W \subset V$ .

Hence  $f$  is continuous.

**Corollary 2.5.** Let  $f : X \rightarrow Y$  be an open function. Then the followings are equivalent;

- (a)  $f$  is rarely continuous
- (b)  $f$  is weakly continuous
- (c)  $f$  is nearly continuous.

**Proof.** Proposition 2.4 shows that (a) implies (b). Since we have known that (b) implies (c) by [Taqdir Husain, §49 proposition 27], it suffices to show that (c) implies (a). Assume that  $f$  is nearly continuous. Then for any  $x$  in  $X$  and any open  $V$  in  $Y$  containing  $f(x)$  there exists an open neighborhood  $U$  of  $x$  in  $X$  such that  $f(U) \subset Int(Cl(V))$ . Let

$$R_v = Int(Cl(V)) - V.$$

Then  $R_v$  is a rare set with  $Cl(R_v) \cap V = \emptyset$ . Hence

$$f(U) \subset Int(Cl(V)) = V \cup R_v.$$

Therefore  $f$  is rarely continuous.

**Proposition 2.6.** Let  $p : X \rightarrow Y$  be a quotient function. Let  $Z$  be topological space and let  $g : X \rightarrow Z$  be a rarely continuous function that is constant on each set  $p^{-1}(\{y\})$ , for  $y$  in  $Y$ . Then  $g$  induces a rarely continuous function  $f : Y \rightarrow Z$  such that  $f \circ p = g$ .

**Proof.** For each  $y$  in  $Y$ , the set  $g(p^{-1}(\{y\}))$  is a one-point set in  $Z$  (since  $g$  is constant on  $p^{-1}(\{y\})$ ). If we let  $f(y)$  denote this point, then we

have defined a function  $f : Y \rightarrow Z$  such that for each  $x \in X$ ,  $f(p(x)) = g(x)$ . To show that  $f$  is rarely continuous, let  $V$  be an open set in  $Z$ . Since  $g$  is rarely continuous, there exists a rare set  $R_v$  in  $Z$  and open  $U$  in  $X$  such that  $g(U) \subset V \cup R_v$ . Since  $p$  is a quotient function,  $p(U)$  is open in  $Y$ . Hence

$$f(p(U)) = g(U) \subset V \cup R_v.$$

Therefore  $f$  is rarely continuous.

**Lemma 2.7.** Let  $f : X \rightarrow Y$  be a function. The following statements are equivalent.

- (a)  $f$  is open rarely continuous
- (b)  $f$  is nearly continuous
- (c) the inverse image of a regular-open subset of  $Y$  is an open set in  $X$ .
- (d) for each open subset  $V$ ,  $f^{-1}(V) \subset Int[f^{-1}(Int(Cl(V)))]$ .

**Proof.** Corollary 2.6 implies the equivalent of (a) and (b). And (b), (c) and (d) are equivalent by [Taqdir Husain, Theorem 11 in §49].

**Theorem 2.8.** Let  $X, Y$  and  $Z$  be spaces,  $A$  be a compact subset of  $X$  and  $B$  be a compact subset of  $Y$ ,  $f : X \times Y \rightarrow Z$  be an open rarely continuous function and  $W$  be a regular-open subset of  $Z$  containing  $f(A \times B)$ . Then there exists an open set  $U$  in  $X$  and an open set  $V$  in  $Y$  such that

$$A \subset U, B \subset V \text{ and } f(U \times V) \subset W.$$

**Proof.** Since  $f$  is open rarely continuous,  $f^{-1}(W)$  is open set in  $X \times Y$  containing  $A \times B$ . For each  $(x, y)$  in  $A \times B$ , there exist open sets  $M$  in  $X$  and  $N$  in  $Y$  such that  $x \in M, y \in N$  and  $M \times N \subset f^{-1}(W)$ . since  $B$  is compact, for a fixed  $x \in A$ ,

there are open sets  $M_1, \dots, M_n$  in  $X$  containing  $x$  and corresponding open sets  $N_1, \dots, N_n$  in  $Y$  such that

$$B \subset Q = N_1 \cup \dots \cup N_n$$

Let

$$P = M_1 \cap \dots \cap M_n.$$

Then  $P$  is open in  $X$ .  $Q$  is open in  $Y$ .  $x \in P$ .  $B \subset Q$ . and  $P \times Q \subset f^{-1}(W)$ . Since  $A$  is compact, there exist open sets  $P_1, \dots, P_m$  in  $X$  and corresponding  $Q_1, \dots, Q_m$  open in  $Y$  such that

$$B \subset V = Q_1 \cap \dots \cap Q_m$$

and

$$A \subset U = P_1 \cup \dots \cup P_m.$$

It follows that  $U$  and  $V$  are the required open sets.

In theorem 2.8. if  $X$  (or  $Y$ ) is locally compact, then  $U$  (or  $V$  respectively) can be chosen so that  $Cl(U)$  (or  $Cl(V)$  respectively) is compact.

**Theorem 2.9.** Let  $f: X \rightarrow Y$  be an open rarely continuous surjective function and  $X$  be a com-

pact space. Then

- (a)  $Y$  is an  $N$ -closed space
- (b)  $Y$  is nearly-compact.

**Proof.** (a) Let  $\{V_\alpha : \alpha \in \nabla\}$  be any open cover of  $Y$ .

Then

$$f^{-1}(V_\alpha) \subset \text{Int}[f^{-1}(\text{Int}(Cl(V_\alpha)))]$$

for each  $\alpha \in \nabla$  by lemma 2.7 (d) and

$$X = \bigcup_{\alpha \in \nabla} f^{-1}(V_\alpha) \subset \bigcup_{\alpha \in \nabla} \text{Int}[f^{-1}(\text{Int}(Cl(V_\alpha)))]$$

Since  $X$  is compact, we have that

$$X = \bigcup_{i=1}^n f^{-1}(\text{Int}(Cl(V_{\alpha_i})))$$

for some finite  $\alpha_i$ . Then

$$Y = f(X) = f(\bigcup_{i=1}^n f^{-1}(\text{Int}(Cl(V_{\alpha_i}))))$$

$$\subset \bigcup_{i=1}^n \text{Int}(Cl(V_{\alpha_i}))$$

Hence  $Y$  is  $N$ -closed.

(b) Let  $\{V_\alpha : \alpha \in \nabla\}$  be any regular-open cover of  $Y$ . Then  $f^{-1}(V_\alpha)$  is open in  $X$  for any  $\alpha \in \nabla$  by lemma 2.7 (c), and  $X = \bigcup_{\alpha \in \nabla} f^{-1}(V_\alpha)$ . Since  $X$  is compact, we have that  $\bigcup_{i=1}^n f^{-1}(V_{\alpha_i})$  covers  $X$

for some finite  $\alpha_i$ . Then

$$Y = f(X) = \bigcup_{i=1}^n V_{\alpha_i}.$$

Hence  $Y$  is nearly-compact.
